How does Na<sub>2</sub>CO<sub>3</sub> affect energy storage capacity?

Na<sub>2</sub>CO<sub>3</sub> doubled the energy storage capacity of the CaO-based materials. "850 °C-900 °C" was best for the Na<sub>2</sub>CO<sub>3</sub> doped CaO in the CaLP-TCES system. Improved CO<sub>2</sub> diffusion leads to the higher energy storage density of the Na<sup>+</sup>-doped materials. doped CaO materials had poorer surface topography, they held much higher ESD over the repeated cycles.

Why do Cao based heat carriers sinter?

The Na<sub>2</sub>CO<sub>3</sub> doped CaO-based heat carriers have a serious tendency of sintering over the cycles, but the Na<sup>+</sup> species provided more basic sites for the promoted CaO materials, and the Na<sup>+</sup> species maybe played a key role like a catalyst to absorb CO<sub>2</sub> during the carbonation process.

How much energy does a neat Cao release?

The "Neat CaO" released about 3000 kJ/kg energy per kilogram of CaO-based materials during the 1st carbonation when operated at either "850 °C-900 °C" or "750 °C-900 °C", while it only showed an ESD of 2500 kJ/kg when operated at "650 °C-900 °C" as shown in Fig. 2 (a).

How are Na<sub>2</sub>CO<sub>3</sub> doped Cao-based heat carriers synthesized?

The Na<sub>2</sub>CO<sub>3</sub> doped CaO-based heat carriers were synthesized by a simultaneous hydration - impregnation method as shown in Figure S1.

What is the binding energy of 10Na<sub>2</sub>CO<sub>3</sub> / CaO?

The binding energies of Ca 2p<sub>3/2</sub> and Ca 2p<sub>1/2</sub> of "Neat CaO" were located at 346.9 eV and 350.5 eV, while the peaks of the binding energy of "10Na<sub>2</sub>CO<sub>3</sub> /CaO" shifted 2 eV lower than the "Neat CaO". The X-ray photoelectron spectroscopy of O 1s was analyzed and displayed in Fig. 13 (b).
